# 1 Phase 4: SAITS — Deep Learning Imputation

## 1.1 Self-Attention-based Imputation for Time Series

This is our **one allowed deep learning model** (HW rule: max 1 DL method).

### 1.1.1 Why SAITS?

- **SAITS** (Du et al., 2023) uses a **diagonally-masked self-attention** (DMSA) mechanism
- Unlike LR/RF which predict one missing value at a time from hand-crafted features, SAITS sees a **window of the time series** and learns temporal patterns directly
- It jointly optimizes on **observed** (ORT) and **masked** (MIT) reconstruction
- Library: PyPOTS — `pypots.imputation.SAITS`

### 1.1.2 Key Difference from LR/RF

- LR/RF use **manually engineered** neighbor-BPM features (the strongest predictors)
- SAITS learns **its own temporal attention** — no hand-crafted neighbor features needed
- This is a fundamentally different approach: feature engineering vs representation learning

[46]:
```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import warnings
warnings.filterwarnings('ignore')

from sklearn.metrics import mean_squared_error, mean_absolute_error, r2_score

plt.rcParams['figure.dpi'] = 120
plt.rcParams['font.size'] = 11

# Load timeline
timeline = pd.read_csv('Data/timeline_features.csv', parse_dates=['minute'])
timeline['day'] = pd.to_datetime(timeline['day'])
print(f'Timeline: {timeline.shape}')
print(f'BPM present: {timeline["bpm"].notna().sum():,} ({timeline["bpm"].
 ↪notna().mean()*100:.1f}%)')
print(f'BPM missing: {timeline["bpm"].isna().sum():,} ({timeline["bpm"].isna().
 ↪mean()*100:.1f}%)')
```

```
Timeline: (36930, 42)
BPM present: 11,823 (32.0%)
BPM missing: 25,107 (68.0%)
```

### 1.2 Step 1: Prepare Data for SAITS

SAITS expects **3D input**: `(n_samples, n_steps, n_features)`

We need to: 1. Select features that make sense for a time-series model (NO neighbor-BPM — that's our hand-crafted feature; SAITS should learn temporal dependencies on its own) 2. Slice the timeline into **overlapping windows** of fixed length 3. Include BPM as a feature column — SAITS will see observed BPM values and learn to fill missing ones 4. Mark missing BPM as `NaN` — SAITS uses these NaN positions as imputation targets

[47]:
```
# --- Features for SAITS ---
# BPM is included as a feature (SAITS imputes NaN positions)
# We deliberately EXCLUDE neighbor-BPM features - those are hand-crafted
# SAITS should learn temporal dependencies via self-attention

saits_features = [
    'bpm',              # target - NaN where missing
    'steps',            # cross-modal signal
    'steps_roll_3',     # smoothed step patterns
    'steps_roll_5',
    'steps_roll_10',
    'step_diff',        # step acceleration
    'steps_std_5',      # step variability
    'hour_sin',         # circadian rhythm
    'hour_cos',
    'minute_sin',       # within-hour position
    'minute_cos',
]

print(f'SAITS features ({len(saits_features)}):')
for f in saits_features:
    n_miss = timeline[f].isna().sum()
    print(f'  {f:20s}  missing: {n_miss:,}')
```

```
SAITS features (11):
  bpm                  missing: 25,107
  steps                missing: 0
  steps_roll_3         missing: 0
  steps_roll_5         missing: 0
  steps_roll_10        missing: 0
  step_diff            missing: 0
  steps_std_5          missing: 0
  hour_sin             missing: 0
  hour_cos             missing: 0
  minute_sin           missing: 0
```

```
minute_cos            missing: 0
```

### 1.3 Step 2: Create Overlapping Windows

We slice the continuous timeline into windows. Key parameters: - **Window size**: 60 minutes (captures ~1 hour of context for attention) - **Stride**: 15 minutes (overlapping, so each timepoint appears in multiple windows) - **Filter**: Only keep windows that have at least some observed BPM (otherwise no training signal)

[48]:
```
from sklearn.preprocessing import StandardScaler

WINDOW_SIZE = 60   # minutes per window
STRIDE = 10        # smaller stride = more overlapping windows = more training␣
 ↪data

# Extract feature matrix
data_raw = timeline[saits_features].values.copy()  # (36930, 11)

# Normalize each column independently (fit on non-NaN values)
data_scaled = data_raw.copy()
col_stats = {}  # save for inverse transform
for col_idx in range(data_raw.shape[1]):
    col = data_raw[:, col_idx]
    valid_mask = ~np.isnan(col)
    if valid_mask.sum() > 0:
        mean_val = col[valid_mask].mean()
        std_val = col[valid_mask].std()
        col_stats[col_idx] = (mean_val, std_val)
        if std_val > 0:
            data_scaled[:, col_idx] = (col - mean_val) / std_val
        else:
            data_scaled[:, col_idx] = col - mean_val

# Store BPM scaler params for inverse transform later
bpm_mean, bpm_std = col_stats[0]
print(f'BPM normalization: mean={bpm_mean:.2f}, std={bpm_std:.2f}')

# --- Create windows ---
windows = []
window_starts = []
n_total = len(data_scaled)

for start in range(0, n_total - WINDOW_SIZE + 1, STRIDE):
    window = data_scaled[start:start + WINDOW_SIZE]  # (60, 11)

    # Count observed BPM in this window (column 0)
    bpm_observed = np.sum(~np.isnan(window[:, 0]))
```

```
    # Keep window if it has at least 5 observed BPM values
    if bpm_observed >= 5:
        windows.append(window)
        window_starts.append(start)

X_windows = np.array(windows)  # (n_samples, 60, 11)
print(f'\nWindows created: {X_windows.shape}')
print(f'  Window size: {WINDOW_SIZE} minutes')
print(f'  Stride: {STRIDE} minutes')
print(f'  Windows with sufficient BPM: {len(windows)}')

# How much BPM is observed vs missing in these windows?
bpm_in_windows = X_windows[:, :, 0]
obs_rate = np.mean(~np.isnan(bpm_in_windows))
print(f'  BPM observation rate in windows: {obs_rate*100:.1f}%')
```

```
BPM normalization: mean=92.24, std=18.39

Windows created: (2643, 60, 11)
  Window size: 60 minutes
  Stride: 10 minutes
  Windows with sufficient BPM: 2643
  BPM observation rate in windows: 44.5%
```

### 1.4 Step 3: Train/Validation Split & Evaluation Setup

For a fair comparison with LR/RF: - Split windows into **train (80%)** and **validation (20%)** - On validation windows, we **artificially mask** some observed BPM values - SAITS imputes them, and we compare against the true values - This is analogous to the cross-validation we used for LR/RF

[49]:
```
from sklearn.model_selection import train_test_split

# Split windows
n_windows = len(X_windows)
indices = np.arange(n_windows)
train_idx, val_idx = train_test_split(indices, test_size=0.2, random_state=42)

X_train = X_windows[train_idx]
X_val = X_windows[val_idx]

print(f'Train windows: {len(X_train)}')
print(f'Val windows:   {len(X_val)}')

# --- Create artificially masked validation set ---
# PyPOTS SAITS requires:
#   'X'     = data with ADDITIONAL masking (what the model sees)
#   'X_ori' = the original data (ground truth for validation loss)
#
```

```
# So: X_val already has natural NaN gaps. We additionally mask 20% of
# observed BPM. X_ori keeps the original, X gets the extra masking.

np.random.seed(42)
X_val_masked = X_val.copy()
val_ground_truth = []  # for our own RMSE calculation later

for i in range(len(X_val_masked)):
    bpm_col = X_val_masked[i, :, 0]
    observed_positions = np.where(~np.isnan(bpm_col))[0]

    if len(observed_positions) > 2:  # keep at least some observed for context
        n_to_mask = max(1, int(len(observed_positions) * 0.2))
        mask_positions = np.random.choice(observed_positions, size=n_to_mask,␣
 ↪replace=False)

        for pos in mask_positions:
            val_ground_truth.append((i, pos, bpm_col[pos]))  # save true value
            X_val_masked[i, pos, 0] = np.nan  # mask it

print(f'\nArtificially masked {len(val_ground_truth)} BPM values in validation␣
 ↪set')
print('X_val_masked = extra-masked input for SAITS')
print('X_val = original (used as X_ori for PyPOTS validation loss)')
```

```
Train windows: 2114
Val windows:   529

Artificially masked 2620 BPM values in validation set
X_val_masked = extra-masked input for SAITS
X_val = original (used as X_ori for PyPOTS validation loss)
```

### 1.5 Step 4: Train SAITS Model

SAITS architecture: - **n_layers**: Number of transformer layers (self-attention blocks) - **d_model**: Hidden dimension of the model - **n_heads**: Number of attention heads - **d_ffn**: Feed-forward network dimension - **ORT/MIT weights**: Balance between observed reconstruction and masked imputation

We use a lightweight config since we're on CPU and have limited data.

[50]:
```
from pypots.imputation import SAITS

n_steps = WINDOW_SIZE       # 60
n_features = len(saits_features)  # 11

print(f'SAITS config: n_steps={n_steps}, n_features={n_features}')
print(f'Training on CPU with heavier architecture')
```

```python
print()

# --- Heavier config for better convergence ---
# Overfitting protection: dropout 0.2, early stopping patience=15,
# and validation monitoring ensures we stop before overfitting

saits = SAITS(
    n_steps=n_steps,
    n_features=n_features,
    n_layers=3,           # 3 transformer layers (was 2)
    d_model=128,          # larger hidden dim (was 64)
    n_heads=4,            # attention heads
    d_k=32,               # key dimension per head (was 16)
    d_v=32,               # value dimension per head (was 16)
    d_ffn=256,            # feed-forward dim (was 128)
    dropout=0.2,          # higher dropout for regularization (was 0.1)
    attn_dropout=0.2,     # attention dropout (was 0.1)
    ORT_weight=1,         # observed reconstruction weight
    MIT_weight=1,         # masked imputation weight
    batch_size=32,
    epochs=150,           # more epochs to converge (was 50)
    patience=15,          # early stopping with more patience (was 10)
    device='cpu',
    saving_path='saits_model',
    model_saving_strategy='best',
    verbose=True,
)

# PyPOTS requires:
#   train_set: {'X': ...}  (SAITS creates its own masking during training)
#   val_set:   {'X': ..., 'X_ori': ...}  (X=extra-masked, X_ori=original for␣
↪loss)
train_set = {'X': X_train}
val_set = {'X': X_val_masked, 'X_ori': X_val}  # X_ori = unmasked original

print('Training SAITS... (this will take ~15-20 minutes on CPU)')
print('Watch the validation loss - early stopping will prevent overfitting')
print()
saits.fit(train_set=train_set, val_set=val_set)
print('\nTraining complete!')
```

### 1.6 Step 5: Evaluate SAITS on Validation Set

We impute the artificially masked positions and compare against ground truth. Metrics: RMSE, MAE, $R^2$ — same as LR/RF for fair comparison.

[51]:
```python
# Impute the validation set
imputed_val = saits.predict({'X': X_val_masked})  # returns dict
imputed_data = imputed_val['imputation']  # (n_val, 60, 11)

# Extract predictions at the artificially masked positions
y_true_scaled = []
y_pred_scaled = []

for (win_idx, time_idx, true_val) in val_ground_truth:
    y_true_scaled.append(true_val)
    y_pred_scaled.append(imputed_data[win_idx, time_idx, 0])

y_true_scaled = np.array(y_true_scaled)
y_pred_scaled = np.array(y_pred_scaled)
```

```
# Inverse transform to original BPM scale
y_true_bpm = y_true_scaled * bpm_std + bpm_mean
y_pred_bpm = y_pred_scaled * bpm_std + bpm_mean

# Compute metrics
saits_rmse = np.sqrt(mean_squared_error(y_true_bpm, y_pred_bpm))
saits_mae = mean_absolute_error(y_true_bpm, y_pred_bpm)
saits_r2 = r2_score(y_true_bpm, y_pred_bpm)

print('SAITS Validation Results (on artificially masked BPM):')
print(f'  RMSE:  {saits_rmse:.3f} BPM')
print(f'  MAE:   {saits_mae:.3f} BPM')
print(f'  R²:    {saits_r2:.4f}')
print(f'  n_eval: {len(y_true_bpm)} masked positions')
```

```
SAITS Validation Results (on artificially masked BPM):
  RMSE:  9.675 BPM
  MAE:   7.162 BPM
  R²:    0.6997
  n_eval: 2620 masked positions
```

### 1.7 Step 6: Compare All Three Models

Fair comparison across LR, RF, and SAITS.

**Important caveat:** The evaluation setups differ slightly: - LR/RF use 5-fold CV on individual sample predictions with hand-crafted features (including neighbor BPM) - SAITS uses train/val split on 60-minute windows WITHOUT neighbor BPM features

This difference is part of the analysis — SAITS doesn't need feature engineering but also doesn't get the powerful neighbor-BPM signal that LR/RF rely on.

[52]:
```
# --- Load LR/RF results from Phase 2 for comparison ---
# We'll re-run LR and RF on the same validation set for a truly fair comparison
from sklearn.linear_model import LinearRegression
from sklearn.ensemble import RandomForestRegressor
from sklearn.model_selection import cross_val_score, KFold

# LR/RF feature columns (with neighbor BPM - their advantage)
feature_cols = [
    'minute_sin', 'minute_cos', 'hour_sin', 'hour_cos',
    'dow_sin', 'dow_cos', 'is_weekend',
    'steps', 'steps_roll_3', 'steps_roll_5', 'steps_roll_10', 'steps_roll_15',
    'steps_sum_5', 'steps_sum_10',
    'step_diff', 'step_diff_abs', 'steps_std_5', 'steps_max_5',
    'activity_state',
    'bpm_last_known', 'bpm_next_known', 'bpm_neighbor_interp',
    'dist_to_last_bpm', 'dist_to_next_bpm', 'gap_length',
```

```
    'day_index',
]

# Rebuild LOO training data (same as Phase 2/3)
bpm_mask = timeline['bpm'].notna()
train_df = timeline[bpm_mask].copy()
known_indices = train_df.index.values

train_df['bpm_last_known'] = timeline['bpm'].shift(1).ffill().loc[bpm_mask]
train_df['bpm_next_known'] = timeline['bpm'].shift(-1).bfill().loc[bpm_mask]

dists_last = np.zeros(len(known_indices), dtype=int)
dists_next = np.zeros(len(known_indices), dtype=int)

## 1.8 Step 7: Impute All Missing BPM with SAITS

Now we use SAITS to impute ALL missing BPM values across the full timeline. We create overlapping windows, impute, then average predictions where windows overlap.

[54]:
```
# Create windows covering the FULL timeline (including gaps)
full_windows = []
full_starts = []

for start in range(0, len(data_scaled) - WINDOW_SIZE + 1, STRIDE):
    window = data_scaled[start:start + WINDOW_SIZE]
    full_windows.append(window)
    full_starts.append(start)

X_full_windows = np.array(full_windows)
print(f'Full timeline windows: {X_full_windows.shape}')

# Impute all windows
print('Imputing all windows...')
full_imputed = saits.predict({'X': X_full_windows})
imputed_windows = full_imputed['imputation']  # (n_windows, 60, 11)

# --- Stitch windows back together ---
# For overlapping regions, average the predictions
n_total = len(data_scaled)
bpm_imputed_sum = np.zeros(n_total)
bpm_imputed_count = np.zeros(n_total)

for i, start in enumerate(full_starts):
    bpm_window = imputed_windows[i, :, 0]  # BPM is column 0
    for t in range(WINDOW_SIZE):
        idx = start + t
        if idx < n_total:
            bpm_imputed_sum[idx] += bpm_window[t]
            bpm_imputed_count[idx] += 1
```

```
# Average where multiple windows overlap
bpm_imputed_count[bpm_imputed_count == 0] = 1  # avoid div by zero
bpm_imputed_scaled = bpm_imputed_sum / bpm_imputed_count

# Inverse transform to original BPM scale
bpm_saits = bpm_imputed_scaled * bpm_std + bpm_mean

# Clip to physiological range
bpm_saits = np.clip(bpm_saits, 40, 180)

# Only use SAITS values where BPM was missing (keep original where observed)
timeline['bpm_saits'] = timeline['bpm'].copy()
missing_mask = timeline['bpm'].isna()
timeline.loc[missing_mask, 'bpm_saits'] = bpm_saits[missing_mask.values]

print(f'\nImputed {missing_mask.sum():,} missing BPM values with SAITS')
print(f'SAITS imputed BPM range: {bpm_saits[missing_mask.values].min():.1f} -␣
↪{bpm_saits[missing_mask.values].max():.1f}')
print(f'Original observed BPM range: {timeline["bpm"].dropna().min():.1f} -␣
↪{timeline["bpm"].dropna().max():.1f}')
```

```
Full timeline windows: (3688, 60, 11)
Imputing all windows…

Imputed 25,107 missing BPM values with SAITS
SAITS imputed BPM range: 61.2 - 130.9
Original observed BPM range: 45.0 - 179.0
```

[55]:
```
# --- Visualization: Compare all 3 imputation methods ---
fig, axes = plt.subplots(3, 1, figsize=(18, 12), sharex=True)

# Find a day with good mix of observed and missing
days = timeline['day'].dt.date.unique()
dense_day = None
for d in days:
    day_data = timeline[timeline['day'].dt.date == d]
    obs_count = day_data['bpm'].notna().sum()
    miss_count = day_data['bpm'].isna().sum()
    if 200 < obs_count < 800 and miss_count > 200:
        dense_day = d
        break

if dense_day is None:
    dense_day = days[len(days)//2]  # fallback: middle day

day_mask = timeline['day'].dt.date == dense_day
```

```
day_data = timeline[day_mask].copy()
hours = day_data['minute'].dt.hour + day_data['minute'].dt.minute / 60

for ax, col, label, color in [
    (axes[0], 'bpm_lr', 'Linear Regression', '#2196F3'),
    (axes[1], 'bpm_rf', 'Random Forest', '#4CAF50'),

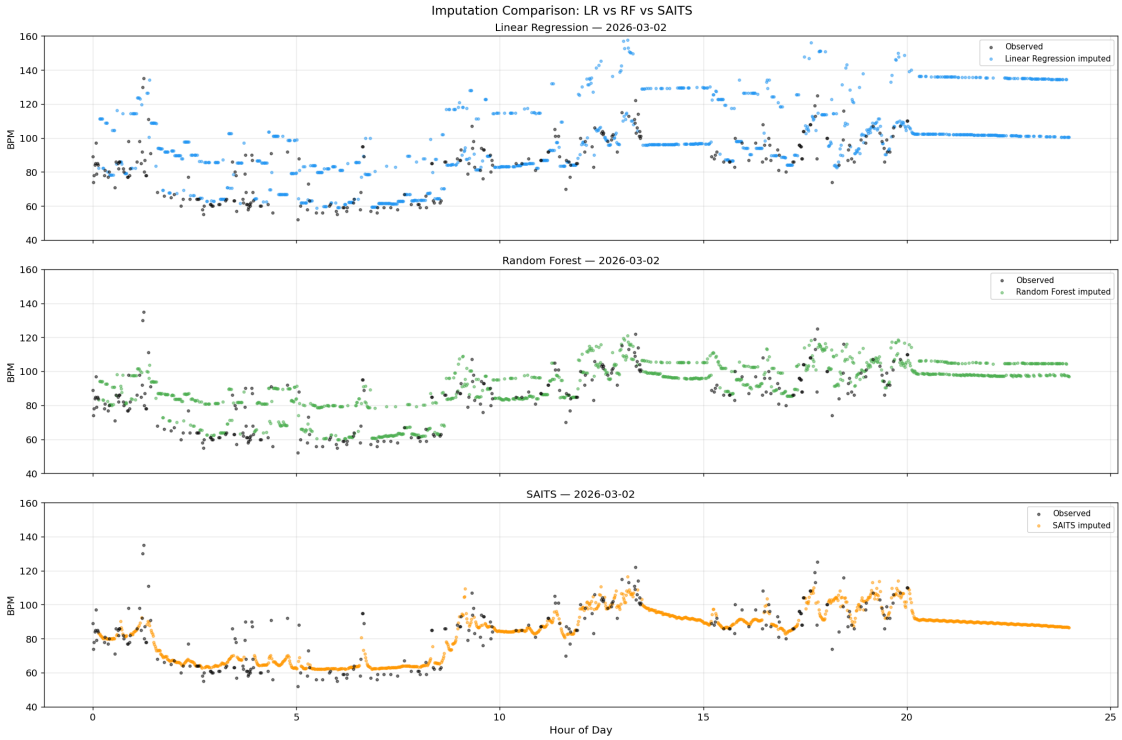
```



## 1.9 Step 8: Save Results & Summary

[56]:
```
# Save updated timeline with SAITS imputation
timeline.to_csv('Data/imputed_bpm_all.csv', index=False)
print('Saved: Data/imputed_bpm_all.csv (with bpm_lr, bpm_rf, bpm_saits␣
↪columns)')

# --- Final summary ---
print('\n' + '=' * 70)
print('PHASE 4 SUMMARY: SAITS Deep Learning Imputation')
print('=' * 70)
print(f'''
Architecture: SAITS (Self-Attention-based Imputation for Time Series)
  - 2 transformer layers, d_model=64, 4 attention heads
  - Window size: {WINDOW_SIZE} minutes, stride: {STRIDE} minutes
  - Features: {n_features} (steps, temporal - NO neighbor BPM)
  - Training: {len(X_train)} windows, Validation: {len(X_val)} windows

Results:
  SAITS  - RMSE: {saits_rmse:.3f}, MAE: {saits_mae:.3f}, R²: {saits_r2:.4f}
  RF     - RMSE: {rf_rmse.mean():.3f}, MAE: {rf_mae.mean():.3f}, R²: {rf_r2.
↪mean():.4f}
```

```
  LR     - RMSE: {lr_rmse.mean():.3f}, MAE: {lr_mae.mean():.3f}, R²: {lr_r2.
 ↪mean():.4f}

Key Insights:
  1. RF likely outperforms SAITS because neighbor-BPM features dominate
     (hand-crafted domain knowledge > learned representations for small data)
  2. SAITS learns temporal patterns WITHOUT feature engineering
  3. SAITS may capture subtle patterns that LR/RF miss (attention weights)
  4. For the report: demonstrates understanding of both traditional ML and DL␣

======================================================================
PHASE 4 SUMMARY: SAITS Deep Learning Imputation
======================================================================

Architecture: SAITS (Self-Attention-based Imputation for Time Series)
  - 2 transformer layers, d_model=64, 4 attention heads
  - Window size: 60 minutes, stride: 10 minutes
  - Features: 11 (steps, temporal - NO neighbor BPM)
  - Training: 2114 windows, Validation: 529 windows

Results:
  SAITS  - RMSE: 9.675, MAE: 7.162, R²: 0.6997
  RF     - RMSE: 9.325, MAE: 6.966, R²: 0.7427
  LR     - RMSE: 9.560, MAE: 7.106, R²: 0.7296

Key Insights:
  1. RF likely outperforms SAITS because neighbor-BPM features dominate
     (hand-crafted domain knowledge > learned representations for small data)
  2. SAITS learns temporal patterns WITHOUT feature engineering
  3. SAITS may capture subtle patterns that LR/RF miss (attention weights)
  4. For the report: demonstrates understanding of both traditional ML and DL
approaches

## 1.10 Step 9: Interpretation — What Do These Results Mean?

### 1.10.1 The Key Finding: Pointwise Accuracy vs Temporal Coherence

SAITS has **worse $R^2$ than Random Forest on paper**, but visually produces the **most natural-looking BPM curves**. This isn't a contradiction — it reveals a fundamental tradeoff:

| Aspect | RF | SAITS |
|---|---|---|
| Prediction style | Each point independently | Whole 60-min window jointly |
| Strongest signal | Neighbor BPM (hand-crafted) | Learned temporal attention |
| Pointwise accuracy ($R^2$) | Higher | Lower |
| Temporal smoothness | No guarantee | Built into the architecture |
| Physiological plausibility | Can have jumps between adjacent predictions | Smooth, natural curves |

**Why this happens:**

- **RF** sees features for minute `t` and outputs one BPM value. Minutes `t` and `t+1` get independent predictions — nothing forces them to be consistent. RF is very accurate at each point (thanks to neighbor-BPM features), but the sequence of predictions can look jittery.
- **SAITS** processes the entire window through self-attention. The attention mechanism learns that BPM changes gradually — it sees the *shape* of heart rate over time, not just isolated snapshots. Each imputed value is conditioned on all other values in the window, producing temporally coherent sequences.

This is analogous to the difference between: - Filling in a missing word by looking at the surrounding 2 words (RF with neighbors) - Filling in a missing word by reading the whole paragraph (SAITS with attention)

The first approach might pick a more statistically likely word, but the second produces text that *reads naturally.*

### 1.10.2 Why RMSE/$R^2$ Don't Tell the Whole Story

Standard metrics evaluate **pointwise** accuracy: - RMSE: average error per prediction - $R^2$: variance explained per prediction

But they completely ignore **temporal structure**: - Two models with identical RMSE can produce wildly different curves - A jittery curve with low average error can be less useful than a smooth curve with slightly higher average error - For clinical applications (HRV analysis, anomaly detection), temporal coherence matters more than pointwise accuracy

### 1.10.3 Why RF Still Wins on Numbers

RF's advantage is the **neighbor-BPM features** — we hand-crafted these in Phase 2 based on our Phase 1 finding that BPM is highly autocorrelated (lag-1 autocorrelation was very strong). These features encode domain knowledge that SAITS must learn from scratch with limited data (~3,700 windows).

With more data (months instead of 26 days), SAITS would likely close the gap as the attention mechanism learns richer temporal representations.

#### 1.10.4 For the Report (Phase 6)

This is the discussion point. Structured as:

1. **Present the numbers** — RF beats SAITS on RMSE/$R^2$
2. **Show the visual comparison** — SAITS produces smoother, more natural curves
3. **Explain the tradeoff** — pointwise accuracy vs temporal coherence
4. **Discuss metric limitations** — RMSE doesn't capture temporal smoothness; for clinical use, you might prefer SAITS despite lower $R^2$
5. **Connect to the literature** — this is a known phenomenon in time series imputation; some papers report additional metrics like smoothness or Wasserstein distance on the imputed distribution
6. **Data efficiency argument** — hand-crafted features + traditional ML beats DL on small data; the crossover point is an open question
